

CONTACTLESS DATA COMMUNICATION SYSTEM, CONTACTLESS
IDENTIFICATION TAG AND CONTACTLESS IDENTIFICATION TAG
CONTROL PROGRAM

RELATED APPLICATIONS

[0001] This application claims priority to Japanese Patent Application No. 2003-070532 filed March 14, 2003 which is hereby expressly incorporated by reference herein in its entirety.

BACKGROUND

[0002] Field of the Invention

[0003] The present invention relates to data communications using a contactless identification tag, and particularly to a contactless communication system that is preferably used to detect that the contactless identification tag attached to baggage (e.g., a package) and so on is improperly detached.

[0004] Description of the Related Art

[0005] In a conventional system, a tag including a shock sensor (refer to Japanese Unexamined Patent Application Publication No. 2002-150248) is attached to a piece of baggage so as to detect that a shock is added to the baggage, by detecting a voltage change caused when the shock sensor is disconnected by the shock beyond a certain amount (refer to Japanese Unexamined Patent Application Publication No. 2002-150249).

[0006] According to the invention as shown in Patent Document 2002-150249, although a shock can be usually detected, it is impossible to detect a shock when the tag is improperly detached because the shock sensor is not disconnected in such a case. Moreover, since the system provides no means to visually identify a tag to which the shock is added after detecting it, it requires complicated work to separate the tag to which the shock is added from other tags to which the shock is not added by detecting it again by means of the detection system.

[0007] According to the invention as shown in Patent Document 2002-150248, the disconnection is detected by using the shock sensor as a part of an antenna. In this case, since a deviation in resonant frequencies blocks communications, it is impossible to discern whether the problem is a breakdown or a shock.

[0008] In consideration of the above-mentioned problems posed by the conventional art, the present invention aims to provide a contactless communication system, a contactless identification tag and a contactless identification tag control program to detect that the contactless identification tag attached to a given object is improperly detached.

SUMMARY

[0009] In order to solve the problems described above, a contactless communication system according to the present invention includes a reader-writer device and a contactless identification tag. The reader-writer device includes a data communication means that is capable of data communications

with the contactless identification tag and an electromagnetic wave transmission means for supplying power that transmits electromagnetic waves for supplying power to the contactless identification tag at the time of data communications by the data communication means. The contactless identification tag includes a driving electric power generation means that generates driving electric power from the electromagnetic waves for supplying power transmitted from the reader-writer device, an attachment means to attach the contactless identification tag to a given object, a detachment detection means to detect whether the contactless identification tag, which is attached to the given object by the attachment means, is detached from the given object or not, and a specific information display means to display specific information based on a detection result obtained by the detachment detection means.

[0010] According to this composition of a first mode of the invention, the reader-writer device does data communications with the contactless identification tag by the data communication means, transmits electromagnetic waves to the contactless identification tag by the electromagnetic wave transmission means for supplying power at the time of data communications by the data communication means. The contactless identification tag generates driving electric power from the electromagnetic waves for supplying power transmitted by the reader-writer device by the driving electric power generation means, attaches the contactless identification tag to a given object by the attachment means, detects whether the contactless identification tag, which is attached to the given object by the attachment means, is detached from the given object or not, and displays the specific information by the specific

information display means, based on a detection result obtained by the detachment detection means.

[0011] Accordingly, it becomes possible to easily visually find out (or discern) if the contactless identification tag is detached by detecting that the contactless identification tag attached to the given object, such as baggage, is detached and displaying that fact. While the term "baggage" is used throughout this application, one skilled in the art will appreciate that terms such as packages, parcels, and the like are to be considered equivalent thereto.

[0012] In this case, the contactless identification tag is such as used in the RFID (Radio Frequency Identification) system, and is generally called a data-carrier. The tag can be in various shapes, such as a label, a card, a coin, and a stick. These shapes are closely related to their applications. For example, the tag can be a keychain-like card or label as a carry-along device. The tag can mainly be stick-shaped as a semiconductor carrier ID. It may be coin-shaped for being sewn in linen goods.

[0013] The contactless identification tag also includes a memory region to exclusively read data or to read and write data freely. Furthermore, the tag of a certain type is workable without any battery by the contactless transmission of electric power from the antenna side.

[0014] Here, the RFID system is an ID system using electric and electromagnetic waves as a carrier. The system enables the contactless identification tag to (1) be portable in size, (2) store the information in an electronic circuit, and (3) perform contactless communications.

[0015] Therefore, the RFID system is used to integrate and share information with a person, object, automobile, etc. that has the contactless identification tag. In other words, necessary information is available to the person, object, or automobile, and new information is added as necessary.

[0016] Representative examples of the RFID system include the following: an electromagnetic coupling system, in which communications with the contactless identification tag are done by using mutual induction of coils in an alternating magnetic field; an electromagnetic induction system, in which communications with the contactless identification tag are done by mainly using electromagnetic waves at a frequency of 250 kHz or below or at a low- to medium-frequency of 13.56 MHz; a microwave system, in which data communications between the antenna at the side of the reader-writer device and the contactless identification tag are done by using electromagnetic waves at a frequency of 2.45 GHz; and an optical system, in which communications with the contactless identification tag are done by using optical transmission from an LED as a source of light to a photo transistor etc. as a light receiver.

[0017] Major access modes are the following: a single access mode, a FIFO (First In First Out) access mode, a multi access mode and a selective access mode.

[0018] In the single access mode, there is one contactless identification tag within an antenna communication region. On the other hand, if there is a plurality of contactless identification tags, which causes a communication error, it is impossible to communicate.

[0019] In the FIFO access mode, it is possible to communicate with one contactless identification tag after another coming into the antenna communication region. Since the contactless identification tag which has completed communications is kept in an access denied status, it is possible to communicate with a new tag coming into the antenna communication region, even if there are a plurality of contactless identification tags having completed communications remaining in the region. If a plurality of contactless identification tags come into the antenna communication region at the same time, which causes a communication error, it becomes impossible to communicate. The access denied status is removed once the contactless identification tag leaves the communication region.

[0020] In the multi access mode, it is possible to communicate with all contactless identification tags, even if there is a plurality of contactless identification tags in the antenna communication region.

[0021] In the selective access mode, it is possible to communicate with only specified contactless identification tags out of a plurality of contactless identification tags within the communication region. This is realized by using a command to allocate a number to each of the contactless identification tags within the communication region and a command to communicate with the specified contactless identification tags based on the allotted numbers.

[0022] A second mode of the invention is different from the first mode of the invention in that the contactless identification tag includes a detection result transmission means to transmit information indicating detachment of the

tag to the reader-writer device when the detachment detection means detects that the contactless identification tag is detached from a given object.

[0023] That is, the contactless identification tag transmits information indicating the detachment to the reader-writer device, when the contactless identification tag is detected as being detached from the given object.

[0024] This enables the reader-writer device to detect that the contactless identification tag is detached from baggage and so on, and thereby facilitating measures to be taken.

[0025] A third mode of the invention is different from the first and the second modes of the invention in that the specific information display means displays information indicating the detachment of the tag as the specific information, when the detachment detection means detects that the contactless identification tag is detached from a given object.

[0026] In other words, the specific information display means displays information indicating the detachment of the tag (by displaying an X-mark or a red screen, for example) as the specific information, when the detachment detection means detects that the contactless identification tag is detached.

[0027] Accordingly, it is possible to easily visually judge the detachment of the contactless identification tag with the displayed information if the contactless identification tag attached to the given object, such as baggage and so on, is wrongly detached, thereby possibly being improperly attached to other baggage and so on.

[0028] A fourth mode of the invention is different from the first through the third modes of the invention in that the detachment detection means

includes a voltage monitoring circuit which is able to monitor a voltage. Here, a part of a circuit wiring composed of the contactless identification tag is coupled to the voltage monitoring circuit, and the wiring is disconnected when the contactless identification tag is detached from a given object, and thereby enabling detection that the contactless identification tag is detached from the given object by detecting a voltage change caused by the disconnection of the wiring.

[0029] That is, the detachment detection means includes the voltage monitoring circuit to monitor the voltage, a part of the circuit wiring composed of the contactless identification tag is coupled to the voltage monitoring circuit, the wiring is disconnected when the contactless identification tag is detached from the given object. Therefore, it is possible to detect that the contactless identification tag is detached from the given object by detecting a voltage change caused by the disconnection of the wiring.

[0030] As a consequence, it is possible to easily detect that the contactless identification tag is detached from a voltage change.

[0031] A fifth mode of the invention is different from the first through the fourth modes of the invention in that the specific information display means includes a display device having memory ability. In other words, the specific information display means has a display device with memory ability. If the display device is of an electrophoresis type having memory ability, it is possible to retain information, if it is once displayed, without consuming any electric power. Therefore, it is possible to keep displaying the information indicating the detachment of the tag. Here, the display device of the electrophoresis type

utilizes electrophoretic mobility. Electrophoretic mobility means a phenomenon of minute particles naturally charged during dispersion (electrophoretic particles), migrating by the Coulomb force when applying an electric field to a liquid medium in which the minute particles are dispersed (a dispersion liquid). The display device of the electrophoresis type has ability to retain images once displayed (referred to as "memory ability" here), so it is possible to retain the images if displayed once, by applying an electric field.

[0032] A sixth mode of the invention is the contactless identification tag in the contactless communication system according to the first mode of the invention. The contactless identification tag includes a driving electric power generation means that generates driving electric power from electromagnetic waves for supplying power transmitted from the reader-writer device, an attachment means to attach the contactless identification tag to a given object, a detachment detection means to detect whether the contactless identification tag attached to the given object by the attachment means is detached from the given object or not and a specific information display means to display the specific information based on the detection result obtained by the detachment detection means.

[0033] The present mode provides the contactless identification tag in the contactless communication system according to the first mode of the invention. Its functional operations being already described, the description is omitted here.

[0034] A seventh mode of the invention is different from the sixth mode of the invention in that the contactless identification tag includes a

detection result transmission means that transmits information indicating the detachment of the tag to the reader-writer device when the detachment detection means detects that the contactless identification tag is detached from a given object.

[0035] The present mode provides the contactless identification tag in the contactless communication system according to the second mode of the invention. Its functional operations being already described, the description is omitted here.

[0036] An eighth mode of the invention is different from the sixth and the seventh modes of the invention in that the specific information display means displays information indicating wrongdoing as the specific information, when the detachment detection means detects that the contactless identification tag is detached from the given object.

[0037] The present mode provides the contactless identification tag in the contactless communication system according to the third mode of the invention. Its functional operations being already described, the description is omitted here.

[0038] A ninth mode of the invention is different from the sixth through eighth modes of the invention in that the detachment detection means includes a voltage monitoring circuit to monitor the voltage, a part of a circuit wiring composed of the contactless identification tag is coupled to the voltage monitoring circuit, the wiring is disconnected when the contactless identification tag is detached from the given object, and thereby enabling detection that the

contactless identification tag is detached from a given object by detecting a voltage change caused by the disconnection of the wiring.

[0039] The present mode provides the contactless identification tag in the contactless communication system according to the fourth mode of the invention. Its functional operations being already described, the description is omitted here.

[0040] A tenth mode of the invention is different from the sixth through the ninth modes of the invention in that the specific information display means includes a display device having memory ability.

[0041] The present mode provides the contactless identification tag in the contactless communication system according to the fifth mode of the invention. Its functional operations being already described, the description is omitted here.

[0042] An eleventh mode of the invention is a program that controls the contactless identification tag according to the sixth mode of the invention. The program includes a detachment detection step that detects whether the contactless identification tag attached to a given object by the attachment means is detached from the given object or not, and a specific information display step that displays specific information based on a detection result obtained as a result of the detachment detection step.

[0043] The present mode provides a program to control the contactless identification tag according to the sixth mode of the invention. Its functional operations being already described, its description is omitted here.

[0044] A twelfth mode of the invention is the program that controls the contactless identification tag and that is different from the eleventh mode of the invention in that the specific information display step includes a detection result transmission step that transmits information indicating the detachment of the tag to the reader-writer device when it is detected that the contactless identification tag is detached from a given object in the detachment detection step.

[0045] The present mode provides a program to control the contactless identification tag according to the seventh mode of the invention. Its functional operations being already described, the description is omitted here.

[0046] A thirteenth mode of the invention is the program that controls the contactless identification tag and that is different from the eleventh and twelfth modes of the invention in that the specific information display step displays information indicating wrongdoing as specific information when it is detected that the contactless identification tag is detached from a given object in the detachment detection step.

[0047] The present mode provides a program to control the contactless identification tag according to the eighth mode of the invention. Its functional operations being already described, the description is omitted here.

BRIEF DESCRIPTION OF THE DRAWINGS

[0048] FIG. 1 is a block diagram showing the composition of a contactless communication system according to an embodiment of the present invention.

[0049] FIG. 2 is a block diagram showing the detailed composition of a reader-writer device 2.

[0050] FIG. 3 is a block diagram showing the detailed composition of a contactless identification tag 3.

[0051] FIG. 4 is a figure showing the composition of detachment detection by a voltage monitoring part 34 and a detachment detection part 35.

[0052] FIG. 5 (a) is a figure showing the circuit composition of the contactless identification tag, while FIG. 5 (b) is a sectional view along the line A-A in FIG. 5 (a).

[0053] FIG. 6 (a) is a sectional view along the line A-A when the contactless identification tag 3 shown in FIG. 5 is attached to a piece of baggage 4, while FIG. 6 (b) is a figure showing the state in which the contactless identification tag 3 is detached from the baggage 4 in the sectional view FIG. 6 (a).

[0054] FIG. 7 is a flow chart showing the function operation of the data communication device 2.

[0055] FIG. 8 is a flow chart showing response operations corresponding to a response request command from the contactless identification tag 3.

DETAILED DESCRIPTION

[0056] An embodiment of the present invention will now be described referring to the accompanying figures. FIGs. 1 through 8 show an embodiment in which a contactless data communication system according to the present

invention is applied to the baggage management operation of a shipping company.

[0057] First, the composition of the contactless data communication system according to the present invention will be described referring to FIG. 1. FIG. 1 is a block figure showing the composition of the contactless data communication system according to the present invention.

[0058] As shown in FIG. 1, a contactless data communication system 1 includes a reader-writer device 2, a contactless identification tag 3 including a plurality of contactless identification tags, and baggage 4 including multiple pieces of baggage.

[0059] The reader-write device 2 writes management information such as a forwarding address and owner of the baggage and so on to the contactless identification tag 3 attached to the baggage 4, reads the management information written in the contactless identification tag 3 to display the fact in a display part, and also displays the information of a false use transmitted from the contactless identification tag 3 in the display part. The contactless identification tag 3 has an attachment part to attach itself to the baggage 4, corresponding to each piece of the baggage 4, and does contactless data communications with the reader-write device 2 by using an ID number so as to manage the baggage 4. In addition, the contactless identification tag 3 has a detection part to detect that it is detached from the baggage 4. The contactless identification tag 3 detects the fact and informs the reader-writer device 2 of the fact when itself is improperly detached from the baggage. The ID number is a particular one for each contactless identification

tag 3 and is stored in a data memory part 33 of the contactless identification tag 3 described later.

[0060] The baggage 4 is baggage to be delivered according to an order of a customer in a shipping company. The contactless identification tag 3 is attached to each piece of baggage.

[0061] The composition of the reader-write device 2 will be described referring to FIG. 2. FIG. 2 is a block figure showing the detailed composition of the reader-write device 2.

[0062] As shown in FIG. 2, the reader-write device 2 includes a data reception part 2a, a data transmission part 2b, a control part 2c, an operation part 2d, a RAM (Random Access Memory) 2e, a ROM (Read Only Memory) 2f, and a display part 2g.

[0063] The data reception part 2a receives information from the contactless identification tag 3 without any direct contact. Thereby, it becomes possible to get the management information related to the baggage 4 and the information indicating that the contactless identification tag is improperly detached, and so on.

[0064] The data transmission part 2b transmits a command to read information, such as the management information stored in the contactless identification tag 3 and the management information to correspond the contactless identification tag 3 to each piece of baggage and so on without any direct contact. According to the embodiment of the present invention, carrier waves at the time of the information transmission are used for supplying electric power to the contactless identification tag 3.

[0065] In this case, according to the embodiment of the present invention, communications between the reader-writer device 2 and the contactless identification tag 3 are done mainly by using the electromagnetic induction system in which electromagnetic waves at a frequency of 250 kHz band or below or at a low- to medium-frequency of 13.56 MHz are used to communicate, and also, the selective access mode is used to communicate with the specified contactless identification tag out of a plurality of the contactless identification tags in the communication region.

[0066] The control part 2 totally controls the operations of the reader-writer device 2 by implementing a control program stored in the ROM 2f by means of a CPU (Central Processing Unit) that is not shown in the figure. The operations to be controlled include data communication processing utilizing the electromagnetic induction system such as receiving data from the contactless identification tag 3 and transmitting data to the contactless identification tag 3 by using the data reception part 2a and the data transmission part 2b. Other examples are changing set values for implementing the control program according to operations of the operation part 2d, and displaying of specific information such as information obtained from the contactless identification tag 3 on the display part 2g.

[0067] The operation part 2d includes operations such as switching power supply and resetting the program. The operation part 2d also includes a set part to set information to be written in the contactless identification tag 3, and so on.

[0068] The RAM 2e is a memory to temporally store necessary data to implement the control program stored in the ROM 2f by means of the CPU of the control part 2c.

[0069] The ROM 2f is a read-only memory in which the control program to totally control the reader-writer device 2 is stored.

[0070] The display part 2g includes a display region of liquid crystal and so on. The display part 2g functions to display information obtained from the contactless identification tag 3, set contents of the reader-writer device 2 at the present time, the status of processing, and so on.

[0071] The composition of the contactless identification tag 3 will now be described referring to FIG. 3. FIG. 3 is a block diagram showing a detailed composition of the contactless identification tag 3.

[0072] As shown in FIG. 3, the contactless identification tag 3 includes a data communication part 3a, a control part 3b, a data memory part 33, a detachment detection part 35, an electrophoresis display part 37, a power supply generation part 38, and a coil antenna 39.

[0073] The data communication part 3a includes a data reception part 30, a data transmission part 31, and the coil antenna 39.

[0074] The data reception part 30 functions to receive data transmitted from the reader-writer device 2, utilizing the electromagnetic induction system.

[0075] The data transmission part 31 has a function to transmit specific data stored in the data memory part 33 to the reader-writer device 2 utilizing the electromagnetic induction system.

[0076] The coil antenna 39 receives electromagnetic waves including data transmitted from the reader-writer device 2 utilizing the electromagnetic induction system.

[0077] The control part 3b includes a data control part 32, a voltage monitoring part 34, and a display processing part 36, so as to control operations of each part of the contactless identification tag 3 by implementing the control program of each part by means of the CPU that is not shown in FIG. 3. According to the embodiment of the present invention, the operation of the contactless identification tag 3 is controlled by the CPU and the control program. In addition, the operations can be controlled by a logic circuit.

[0078] The data control part 32 controls data transmission and reception in the data communication part 3a, controls memory processing of received data, and so on.

[0079] The voltage monitoring part 34 monitors a voltage of a predetermined circuit in the contactless identification tag 3.

[0080] The display processing part 36 controls the display of specific information on the electrophoresis display part 37 according to a command from the data control part 32.

[0081] The data memory part 33 functions to store specific information, such as management information received from the reader-writer device 2 in its own memory. According to the embodiment of the present invention, the above-mentioned control program is also stored in the memory.

[0082] The detachment detection part 35 functions to detect that the contactless identification tag 3 once attached to the baggage 4 is detached, as a voltage change in the voltage monitoring part 34.

[0083] The electrophoresis display part 37 is a display device using the above-mentioned phenomenon of electrophoretic mobility.

[0084] The power supply generation part 38 generates power from electromagnetic waves transmitted from the reader-writer device 2 and supplies the power to each part described above.

[0085] The compositions of the voltage monitoring part 34 and the detachment detection part 35 will now be described referring to FIG. 4. FIG. 4 is a figure showing the composition of detachment detection by the voltage monitoring part 34 and the detachment detection part 35.

[0086] As shown in FIG. 4, the detachment detection part 35 includes a first detective resistor part 35a and a second detective resistor part 35b. One end of the wiring of the first detective resistor part 35a is coupled to the power supply and the other end is coupled to the second detective resistor part 35b. One end of the wiring of the second detective resistor part 35b is coupled to a ground part of a circuit and the other end is coupled to the first detective resistor part 35a. The wiring extending from the joint part of the first detective resistor part 35a and the second detective resistor part 35b is coupled to the voltage monitoring part 34.

[0087] That is, a voltage E_3 at the joint part divided by the first detective resistor part 35a and the second detective resistor part 35b is monitored by the voltage monitoring part 34.

[0088] Next, a detailed composition of the contactless identification tag 3 will be described referring to FIGs. 5 and 6.

[0089] FIG. 5 (a) is a figure showing the circuit composition of the contactless identification tag, FIG. 5 (b) is a sectional view along the line A-A in FIG. 5(a). FIG. 6 (a) is a sectional view along the line A-A when the contactless identification tag 3 shown in FIG. 5 (a) is attached to the baggage 4. FIG. 6 (b) is a figure showing the state in which the contactless identification tag 3 shown in FIG. 5 (a) is detached from the baggage 4 in the sectional view of FIG. 6 (a).

[0090] As shown in FIG. 5 (a), the circuit composition of the contactless identification tag 3 includes a substrate 300b and a coil antenna 39. Formed on the substrate 300b, the coil antenna 39 is made of a whirl-like (concentric) metal wire with one stroke sketch (continuous) along the surrounding of the substrate 300b. According to the embodiment of the present invention, the coil antenna 39 is formed by the ink-jet method using a metal ink.

[0091] At the center of the substrate 300b, the control part 3b is mounted as an IC chip, and the electrophoresis display part 37 is also mounted. Coupled to the control part 3b with a wiring 300a as shown in FIG. 5 (b), a detachment detection circuit part 300 is provided. In the detachment detection circuit part 300, a wiring 300d of the first detective resistor part 35a is formed so that it can be conductive to the wiring 300a, while being adjacent to the wiring 300a. An adhesion part 300c in the figure adheres the contactless identification tag 3 to the baggage 4.

[0092] That is, as shown in FIG. 6 (a), the contactless identification tag 3 is adhered to the baggage 4 by the adhesion part 300c. Here, the

adhesion part 300e of the first detective resistor part 35a is formed in such a way as it can be separated from the other adhesion part 300c. As shown in FIG. 6 (b), when the contactless identification tag 3 is detached from the baggage 4, the first detective resistor part 35a, accompanied by the wiring 300d and the adhesion part 300e, is left on the baggage 4, separated from the body of the contactless identification tag 3, because the wiring 300d is adhered to the wiring 300a with weaker adhesion strength with that to the adhesive part 300c.

[0093] Thus, the first detective resistor part 35a is separated from the circuit shown in FIG. 4 when the contactless identification tag 3 is detached from the baggage 4. Consequently, the voltage divided by the first detective resistor part 35a and the second detective resistor part 35b is not divided any more, so that the voltage E_3 changes. The voltage change is detected by the voltage monitoring part 34, which indicates that the contactless identification tag 3 is detached from the baggage 4.

[0094] The function of the contactless data communication system 1 will now be described in greater detail.

[0095] Here, according to the embodiment of the present invention, the contactless data communication system 1 is applied to the baggage management of a shipping company. The system aims to check whether a contactless identification tag is detached from a piece of baggage or not and whether a false tag is used or not.

[0096] The contactless identification tag 3 is attached to the baggage 4 in advance. Then information to be written in the contactless identification tag 3, which is attached to each piece of the baggage 4 to be shipped, is set by the

operation part 2d of the reader-writer device 2. Here, examples of the information to be set include a baggage sender, a baggage type, a baggage destination, an expected shipping date, and so on. After finishing setting the information, the set information is transmitted to the contactless identification tag 3 having each targeted ID number via the data transmission part 2b.

[0097] On the contactless identification tag 3 side, when it receives a response request signal from the reader-writer 2, it generates driving electric power from carrier waves of the signal by the power supply generation part 38, and supplies the power to each part of the contactless identification tag 3. Then the information transmitted from the reader-writer device 2 is received via the data reception part 3a according to the control of the data control part 32, to which electric power is given through the above mentioned step, and is stored in a non-volatile memory by the data memory part 33. Furthermore, the information, such as a baggage type, a baggage destination, and an expected shipping date is respectively displayed in letters on the electrophoresis display device 37 by the information display processing part 36, based on the stored information. Finally, a response signal indicating that all of this series of operations have been completed is transmitted to the reader-writer device 2 via the data transmission part 31. Here, electric power is not necessary to retain the display of the information because of the features of the electrophoresis display device 37.

[0098] When the contactless identification tag 3 is detached from the baggage 4, the first detective resistor part 35a is separated from the body, as shown in FIG. 6 (b). Then, in this state, if the contactless identification tag 3

receives the response request signal from the reader-writer device 2, it generates driving electric power from carrier waves of the signal in the power supply generation part 38 and supplies the power to each part of the contactless identification tag 3, in the same way as described above. Thereby, in the voltage monitoring part 34, to which electric power is supplied, a change of the voltage E_3 is detected, and it is informed to the data control part 32. When the data control part 32 receives the information, it judges that the contactless identification tag 3 is detached from the baggage 4, and transmits a command to the display processing part 36 to make the electrophoresis display device 37 display the information indicating the detachment.

[0099] In this case, the display is such that clearly shows the state of the contactless identification tag 3, for example, a display of a large X-mark on the display part or a display of the whole screen in red or other bright colors.

[0100] Next, the contactless identification tag 3 transmits the information indicating that the contactless identification tag 3 is detached from the baggage 4 and its own ID number to the reader-writer device 2 via the data transmission part 31, by means of the control part 3b. When the reader-writer device 2 receives the information, the control part 2c judges that the contactless identification tag 3 of the responding ID number is detached from the baggage 4, and the information is displayed on the display part 2g. Seeing the displayed information, an operator of the reader-writer device 2 would check whether the contactless identification tag 3 is detached from the baggage 4 or not, or whether the contactless identification tag 3 once detached is wrongly (or improperly) used again (e.g., reattached to another, wrong, baggage 4).

[0101] When the contactless identification tag 3 is normally attached to the baggage 4, the contactless identification tag 3 only transmits its own ID number on receiving the response request signal from the reader-writer device 2. Thereafter, data communications between the contactless identification tag 3 and the reader-writer device 2, such as a command transmitted from the reader-writer device 2 and a response from the contactless identification tag 3 responding to the request, continue.

[0102] Here, there are various kinds of command, such as the response request command as described above, and also a data writing command to write the management information into the contactless identification tag 3, and so on.

[0103] The flow of operations of the reader-writer device 2 will be described referring to FIG. 7. FIG. 7 is a flow chart showing operations of the reader-writer device 2.

[0104] As shown in FIG. 7, the operations start with a step S700. The reader-writer device transmits a response request signal to the contactless identification tag 3 via the data transmission part 2b by means of the control part 2c, which carries the process forward to a step S702.

[0105] In the step S702, it is judged whether a response from the contactless identification tag 3 is received or not. In the case of "Yes", that is, it is judged that the response is transmitted within the specific time, and the process moves on to a step S704. If "No", the process moves back to the step S700.

[0106] In the step S704, the contents of response from the responding contactless identification tag 3 is analyzed by the control part 2c, which carries the process forward to a step S706.

[0107] In the step S706, it is judged whether the contactless identification tag 3 is detached from the baggage 4 or it is normally attached to the baggage 4, based on the analysis by the control part 2c. If "Yes", that is, it is judged that it is detached, the process moves on to a step S708. If "No", the process moves on to a S712.

[0108] In the step S708, information indicating that the responding contactless identification tag 3 is detached from the baggage 4 is displayed on the display part 2g, which carries the process forward to a step S710.

[0109] In the step 710, communications with the targeted contactless identification tag 3 are suspended by the control part 2c, which carries the process to the step S700.

[0110] On the other hand, in the step S712, normal communications with the responding contactless identification tag 3 are performed by to the control part 2c, which carries the process forward to a step S714.

[0111] In the step S714, it is judged whether communications with the contactless identification tag 3 have completed or not by the control part 2c. If "Yes", that is, it is judged that the communication has completed, the process moves back to the step S700. If "No", the process moves on to the step S712.

[0112] The flow of the response function of the contactless identification tag 3 to a response request command will now be described

referring to FIG. 8. FIG. 8 is a flow chart showing the response function of the contactless identification tag 3 to a response request command.

[0113] As shown in FIG. 8, the operations start with a step S800. The contactless identification tag receives a response request command via the data reception part 30, which carries the process forward to a step 802.

[0114] In the step S802, it is judged whether a voltage change of the voltage E_3 is detected or not by the voltage monitoring part 34. If "Yes", that is, it is judged that it is detected, the process moves on to a step S804. If "No", the process moves on to a step S810.

[0115] In the step S804, it is judged that the contactless identification tag 3 is detached from the baggage 4, which carries the process forward to a step S806.

[0116] In the step S806, information indicating that the contactless identification tag 3 is detached from the baggage 4 is displayed on the electrophoresis display part 37 by the display processing part 36, which carries the process forward to a step S808.

[0117] In the step 808, an ID number and information indicating that the contactless identification tag 3 is detached from the baggage 4 are read out from the data memory part 33 via the data transmission part 31 by the data control part 32, and transmitted to the reader-writer device 2, which completes the operation.

[0118] On the other hand, in the step S802, when a change of the voltage E_3 is not detected by the voltage monitoring part 34, which carries the process to the step S810, normal information such as management information

read out from the data memory part 33 is displayed by the display processing part 36 on the electrophoresis display part 37, which carries the process forward to a step S812.

[0119] In the step S812, the ID number, which is read out from the data memory part 33 via the data transmission part 31 by the data control part 32, is transmitted to the reader-writer device 2, which completes the operations.

[0120] As described above, since it is possible to detect that the contactless identification tag 3 is detached from the baggage 4 and display this fact on the electrophoresis display part 37 of the contactless identification tag 3, it is easy to visually find out if the contactless identification tag 3 is broken by an accident or the contactless identification tag 3 once detached is being improperly reused on another but wrong baggage 4..

[0121] Moreover, because the contactless identification tag 3 transmits information indicating the detachment to the reader-writer device 2 when it is detected that the contactless identification tag 3 attached to the baggage 4 is detached, and because also the reader-writer device 2 displays the information indicating the detachment of the contactless identification tag 3 on the display part 2g, an operator of the reader-writer device 2 can easily see that the contactless identification tag 3 is detached from the baggage 4.

[0122] The data communication operation with the contactless identification tag 3 by the data reception part 2a and the data transmission part 2b by means of the control part 2c shown in FIG. 2 corresponds to the data communication operation means described in the first mode of the invention. The supply operation of electromagnetic waves for supplying power by

transmitting carrier waves by the data transmission part 2b by means of the control part 2c corresponds to the electromagnetic wave transmission means for supplying power described in the first mode of the invention. The detection operation to detect the detachment of the contactless identification tag 3 from the baggage 4 by the voltage monitoring part 34 and the detection part 35 shown in FIG. 3 corresponds to the detachment detection means described in the first through fourth modes of the invention and the sixth through ninth modes of the invention. The operation to display the information by the display processing part 36 and the electrophoresis display part 37 corresponds to the specific information display means described in any one of the first, third, fifth, sixth, eighth and tenth modes of the invention. The power supply generation part 38 corresponds to the driving electric power generation means described in the first and sixth modes of the invention. The adhesion parts 300c and 300e shown in FIGs. 5 and 6 correspond to the attachment means described in any one of the first, sixth, and eleventh modes of the invention.

[0123] According to the above-mentioned embodiment of the present invention, it is detected that the contactless identification tag 3 is detached from the baggage 4 by a voltage change by the voltage monitoring part 34 and the detachment detection part 35, as described above. In addition, it is possible to detect that the contactless identification tag 3 is detached from the baggage 4 by any other means, such as detecting a change in electric current values or using a switch to count the number of detachment of the contactless identification tag 3.

[0124] Moreover, according to the above-mentioned embodiment of the present invention, a voltage is changed by separating a substrate pattern including a resistor element from the body of the contactless identification tag 3 when the contactless identification tag 3 attached to the baggage 4 is detached. In addition, voltage values can be changed by some other means.
